Classically, an *L*-function is a meromorphic function on \mathbb{C} (often entire) associated to a mathematical object *X* (usually coming from geometry, representation theory, number theory ...).

The construction of a complex *L*-function usually goes *mutatis mutandis* as follows:

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

Classically, an *L*-function is a meromorphic function on \mathbb{C} (often entire) associated to a mathematical object *X* (usually coming from geometry, representation theory, number theory ...).

The construction of a complex *L*-function usually goes *mutatis mutandis* as follows:

(i) Write a series (a so-called Dirichlet series) of the form

$$L(s) = L(X,s) = \sum_{n=1}^{+\infty} \frac{a_n}{n^s}$$

where the coefficients $\{a_n\}_{n\geq 1} \subset \mathbb{C}$ satisfy growth conditions that ensure that *L* defines a holomorphic function on the right half-plane $\{\operatorname{Re}(s) > r\} \subset \mathbb{C}$ for some $r \in \mathbb{R}$, $r \geq 1$. The coefficients $\{a_n\}$ encode information about the object *X*. (ii) Find a gamma factor γ (i.e. a suitable meromorphic function on C, often related to the usual gamma function Γ) such that the function Λ(s) := L(s) · γ(s) extends to a meromorphic function on C satisfying a functional equation of the form

$$\Lambda(s) = c_L \cdot \Lambda(k-s)$$

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ・ うへつ

for some $k \ge r$ and $c_L \in \mathbb{C}$, $c_L \ne 0$. Usually $k \in \mathbb{Z}$.

(ii) Find a gamma factor γ (i.e. a suitable meromorphic function on C, often related to the usual gamma function Γ) such that the function Λ(s) := L(s) · γ(s) extends to a meromorphic function on C satisfying a functional equation of the form

$$\Lambda(s) = c_L \cdot \Lambda(k-s)$$

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ・ うへつ

for some $k \ge r$ and $c_L \in \mathbb{C}$, $c_L \ne 0$. Usually $k \in \mathbb{Z}$.

(iii) Use the above functional equation to extend L to a meromorphic function on \mathbb{C} . which we will denote again by L = L(X, s).

One common (and vague!) way to answer this question is that L-functions contain a lot of arithmetic information about the object X.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

One common (and vague!) way to answer this question is that L-functions contain a lot of arithmetic information about the object X.

A prototypical example of this phenomenon is the so-called **analytic class number formula** (due to Dirichlet, Kummer, Dedekind, ...).

If K is a number field (i.e. a finite field extension of \mathbb{Q}) one can attach to K the so-called Dedekind zeta function ζ_K , prove the analytic continuation and functional equation and finally show that

$$\lim_{s \to 1} (s-1)\zeta_{\mathcal{K}}(s) = \frac{2^{r_1} \cdot (2\pi)^{r_2} \cdot \operatorname{Reg}_{\mathcal{K}} \cdot h_{\mathcal{K}}}{w_{\mathcal{K}} \cdot \sqrt{|\Delta_{\mathcal{K}}|}}$$

One common (and vague!) way to answer this question is that L-functions contain a lot of arithmetic information about the object X.

A prototypical example of this phenomenon is the so-called **analytic class number formula** (due to Dirichlet, Kummer, Dedekind, ...).

If K is a number field (i.e. a finite field extension of \mathbb{Q}) one can attach to K the so-called Dedekind zeta function ζ_K , prove the analytic continuation and functional equation and finally show that

$$\lim_{s \to 1} (s-1)\zeta_{\mathcal{K}}(s) = \frac{2^{r_1} \cdot (2\pi)^{r_2} \cdot \operatorname{Reg}_{\mathcal{K}} \cdot \underline{h_{\mathcal{K}}}}{w_{\mathcal{K}} \cdot \sqrt{|\Delta_{\mathcal{K}}|}}$$

Many important open conjectures in number theory can be phrased in terms of L-functions.

Dirichlet characters

Let $N \in \mathbb{Z}$, $N \ge 2$. A Dirichlet character defined modulo N is a function $\chi : \mathbb{Z} \to \mathbb{C}$ such that

•
$$\chi(1) = 1, \ \chi(N) = 0$$

•
$$\chi(n) = \chi(m)$$
 if $n \equiv m \mod (N)$

•
$$\chi(nm) = \chi(n)\chi(m)$$
 for all $n, m \in \mathbb{Z}$

We say that χ is trivial if $\chi(\mathbb{Z}) \subseteq \{0, 1\}$.

The constant function $\mathbf{1}: \mathbb{Z} \to \mathbb{C}$ $(\mathbf{1}(n) = 1$ for all $n \in \mathbb{Z})$ is the unique (and trivial!) Dirichlet character modulo 1.

The Dirichlet L-series associated to χ is

$$L(\chi,s) = \sum_{n=1}^{+\infty} \frac{\chi(n)}{n^s}$$

This series converges for $\operatorname{Re}(s) > 1$. Actually $L(\chi, s)$ defines a holomorphic function for $\operatorname{Re}(s) > 0$ if χ is not trivial. In this case $L(\chi, 1) \neq 0$.

If χ is trivial then $(s-1) \cdot L(\chi, s)$ can be continued to a holomorphic function for $\operatorname{Re}(s) > 0$ (not vanishing at s = 1).

These two different behaviours are the key ingredients that allowed Dirichlet to prove his theorem about primes in arithmetic progressions in 1837.

Riemann ζ function

When $\chi = \mathbf{1}$ then $L(\mathbf{1}, s) = \zeta(s)$ is the Riemann zeta function.

Euler proved (in 1737) that it admits a product expansion as

$$\zeta(s) = \prod_{p} \frac{1}{1 - p^{-s}} \quad \text{for } \operatorname{Re}(s) > 1$$

Riemann ζ function

When $\chi = \mathbf{1}$ then $L(\mathbf{1}, s) = \zeta(s)$ is the Riemann zeta function.

Euler proved (in 1737) that it admits a product expansion as

$$\zeta(s) = \prod_{p} \frac{1}{1 - p^{-s}} \qquad \text{for } \operatorname{Re}(s) > 1$$

In 1859 Riemann proved that:

(i) there is an entire function ξ such that when $\operatorname{Re}(s) > 1$ it holds

$$\xi(s) = \frac{1}{2} \cdot s(s-1) \cdot \pi^{-s/2} \cdot \Gamma\left(\frac{s}{2}\right) \cdot \zeta(s)$$

(ii) the function ξ satisfies $\xi(s) = \xi(1-s)$ for all $s \in \mathbb{C}$.

Hence ζ can be continued to a meromorphic function on \mathbb{C} with a unique simple pole at s = 1

Riemann hypothesis

It is not too hard to prove that

(i)
$$\Gamma(n+1) = n!$$
 and $\Gamma\left(n+\frac{1}{2}\right) = \frac{(2n)!}{4^n \cdot n!} \sqrt{\pi}$ for $n \in \mathbb{N}$

(ii) Γ has simple poles at s = -n for $n \in \mathbb{N}$ and is holomorphic elsewhere.

▲□▶ ▲□▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへぐ

Riemann hypothesis

It is not too hard to prove that

(i)
$$\Gamma(n+1) = n!$$
 and $\Gamma(n+\frac{1}{2}) = \frac{(2n)!}{4^n \cdot n!} \sqrt{\pi}$ for $n \in \mathbb{N}$

(ii) Γ has simple poles at s = -n for $n \in \mathbb{N}$ and is holomorphic elsewhere.

Since $\zeta(s) \neq 0$ when $\operatorname{Re}(s) > 1$, we obtain that for $\operatorname{Re}(s) < 0$ it can happen $\zeta(s) = 0$ if and only if s = -2n for $n \in \mathbb{Z}_{\geq 1}$. These are the so-called *trivial* zeroes of ζ . The interesting zeroes of ζ lie in the strip $S = \{0 \leq \operatorname{Re}(s) \leq 1\}$ and $\zeta(s_0) = 0$ for some $s_0 \in S$ if and only if $\zeta(1 - s_0) = 0$.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

Conjecture (Riemann, 1859)

The non-trivial zeroes of ζ all lie on the critical line $\operatorname{Re}(s) = \frac{1}{2}$.

Bernoulli numbers and special values

Thanks to Euler we know that for all $n \in \mathbb{Z}_{\geq 1}$

$$\zeta(2n) = \frac{(-1)^{n+1} \cdot (2\pi)^{2n} \cdot B_{2n}}{2 \cdot (2n)!}$$

where $B_k \in \mathbb{Q}$ denotes the k - th Bernoulli number.

These rational numbers are defined via the equality of formal power series in $\mathbb{Q}[[X]]$.

$$\frac{X}{\exp(X)-1} = \sum_{k=0}^{+\infty} B_k \cdot \frac{X^k}{k!}$$

This also means that, for $n \in \mathbb{Z}_{\geq 1}$

$$\zeta(1-2n)=-\frac{B_{2n}}{2n}\in\mathbb{Q}$$

A D > 4 回 > 4 □ > 4

is a rational number!

If χ is a Dirichlet character modulo N, we define generalized Bernoulli numbers $B_{n,\chi} \in \mathbb{Q}[\chi]$ via a modified generating function

$$\sum_{a=1}^{N} \frac{\chi(a) \cdot X \cdot \exp(aX)}{\exp(NX) - 1} = \sum_{n=0}^{+\infty} B_{n,\chi} \frac{X^n}{n!}$$

And one can prove that for $k \ge 1$

$$L(\chi, 1-k) = -\frac{B_{k,\chi}}{k} \in \mathbb{Q}[\chi]$$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

is an algebraic number!

 $\mathbb{R}=$ completion of \mathbb{Q} with respect to the Euclidean absolute value (Archimedean)

Are there other absolute values on \mathbb{Q} ? If *p* is a prime number and $x = r/s \in \mathbb{Q}$, we can set

$$|x|_p = c^{v_p(r) - v_p(s)}$$

where $c \in (0,1)$. This new absolute value satisfies a strong triangular inequality (we say it is non-Archimedean)

 $|x+y|_p \le \max\{|x|_p, |y|_p\}$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

One can complete \mathbb{Q} with respect to $|\cdot|_p$, obtaining a field denoted by \mathbb{Q}_p , called field of *p*-adic numbers. An element $\alpha \in \mathbb{Q}_p$ can be written uniquely as

0

$$\sum_{n=-M}^{+\infty} a_n \cdot p^n$$

with $a_n \in \{0, 1, \dots, p-1\}$. Inside \mathbb{Q}_p we have the subring

$$\mathbb{Z}_{p} = \{ \alpha \in \mathbb{Q}_{p} \mid |\alpha|_{p} \leq 1 \} \supset \mathbb{Z}$$

known as the ring of *p*-adic integers.

We can thus see Dirichlet characters taking values in an algebraic closure $\overline{\mathbb{Q}}_p$ of \mathbb{Q}_p (after fixing an embedding $\overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}}_p$) and study them *p*-adically.

In particular it makes sense to ask whether there exist a (continuous/analytic) function

$$L_{p,\chi}:\mathbb{Z}_p\to \overline{\mathbb{Q}}_p$$

such that for $k \ge 1, k \in \mathbb{Z} \subset \mathbb{Z}_p$ it holds

$$L_{p,\chi}(1-k) = L(\chi, 1-k) \cdot \{\text{explicit factor at } p\}$$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

The existence of such a function is suggested by the many congruences satisfied by Bernoulli numbers.

Kubota-Leopoldt *p*-adic *L*-function

Theorem (Kubota-Leopoldt, 1964)

Let χ be a (p-adic) Dirichlet character. Then there is a continuous function $L_{p,\chi}: \mathbb{Z}_p \smallsetminus \{1\} \rightarrow \overline{\mathbb{Q}}_p$ such that for all $k \in \mathbb{Z}_{\geq 1}$ it holds

$$L_{p,\chi}(1-k) = -(1-\chi\omega^{-k}(p)\cdot p^{k-1})\cdot \frac{B_{k,\chi}}{k} =$$
$$= (1-\chi\omega^{-k}(p)\cdot p^{k-1})\cdot L(\chi\omega^{-k}, 1-k)$$

where $\omega : \mathbb{Z}_p \to \mathbb{Z}_p$ denotes the Teichmüller character

$$\omega(s) = \lim_{n \to +\infty} s^{p^n} \in \mu_{p-1} \cup \{0\} \subset \mathbb{Z}_p$$

Moreover if χ is non-trivial, $L_{p,\chi}$ extends to a continuous function on \mathbb{Z}_p .

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ・ うへつ

One construction of $\overline{L_{p,\chi}}$

- Write χ = ψη with ψ primitive of conductor p^m and η primitive of conductor N with p + N.
- Define a *p*-adic *pseudomeasure* $\mu_{p,\eta}$ on \mathbb{Z}_p^{\times} and let

$$L_{p,\chi}(s) = \int_{\mathbb{Z}_p^{\times}} \psi \omega^{-1}(x) \cdot \langle x \rangle^{-s} \cdot \mathrm{d}\mu_{p,\eta}$$

Show that

$$L_{p,\chi}(1-k) = (1-\chi\omega^{-k}(p)\cdot p^{k-1})\cdot L(\chi\omega^{-k}, 1-k)$$

One construction of $L_{ m ho,\chi}$

- Write χ = ψη with ψ primitive of conductor p^m and η primitive of conductor N with p + N.
- Define a *p*-adic *pseudomeasure* $\mu_{p,\eta}$ on \mathbb{Z}_p^{\times} and let

$$L_{p,\chi}(s) = \int_{\mathbb{Z}_p^{\times}} \psi \omega^{-1}(x) \cdot \langle x \rangle^{-s} \cdot \mathrm{d}\mu_{p,\eta}$$

• Show that

$$L_{p,\chi}(1-k) = (1-\chi\omega^{-k}(p)\cdot p^{k-1})\cdot L(\chi\omega^{-k}, 1-k)$$

Remark

A measure on \mathbb{Z}_p^{\times} with values in \mathbb{Z}_p can be thought as an element of

$$\operatorname{Hom}_{\mathbb{Z}_p}^{cts}(\mathcal{C}(\mathbb{Z}_p^{\times},\mathbb{Z}_p),\mathbb{Z}_p)\cong\mathbb{Z}_p[[\mathbb{Z}_p^{\times}]]$$

L-functions attached to modular forms

Let $f \in S_k(N, \chi)$ be a normalized eigenform of level N, weight k and character χ . Then f has a q-expansion as

$$f = \sum_{n=1}^{+\infty} a_n q^n \qquad q = \exp(2\pi i z), \text{ Im}(z) > 0$$

and the L-function associated to f is not surprisingly defined (at least for ${\rm Re}(s)>k/2+1)$

$$L(f,s) = \sum_{n=1}^{+\infty} \frac{a_n}{n^s} = \prod_p \frac{1}{1 - a_p p^{-s} + \chi(p) p^{k-1-2s}} =$$
$$= \prod_{p|N} \frac{1}{1 - a_p p^{-s}} \times \prod_{p+N} \frac{1}{(1 - \alpha_p^1 p^{-s})(1 - \alpha_p^2 p^{-s})}$$

It extends to a holomorphic function on \mathbb{C} and satisfies a functional equation $s \leftrightarrow k - s$.

Triple product *L*-functions - classical case

Let f, g, h be normalized eigenforms of level N_f, N_g, N_h , character χ_f, χ_g, χ_h , weight k, l, m respectively. Let $N \coloneqq \operatorname{lcm}(N_f, N_g, N_h)$. Write

$$f = \sum_{n=1}^{+\infty} a_n q^n \qquad g = \sum_{n=1}^{+\infty} b_n q^n \qquad h = \sum_{n=1}^{+\infty} c_n q^n$$

and set

$$L(f \times g \times h, s)_{p} \coloneqq \prod_{\eta \in \{1,2\}^{\{1,2,3\}}} \frac{1}{(1 - \alpha_{p}^{\eta(1)} \beta_{p}^{\eta(2)} \gamma_{p}^{\eta(3)} \cdot p^{-s})} \quad \text{for } p + N$$
$$L(f \times g \times h, s) \coloneqq \prod_{p \neq N} L(f \times g \times h, s)_{p}$$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ◆ ○ ◆

Garrett and Harris-Kudla proved that $L(f \times g \times h, s)$ admits analytic continuation to \mathbb{C} and functional equation $s \leftrightarrow k + l + m - 2 - s$.

My PhD project is related to the construction of a *p*-adic *L*-function of three variables (k, l, m) that should interpolate (the algebraic part) of the special values

$$L(\mathbf{f}_k \times \mathbf{g}_l \times \mathbf{h}_m, \frac{k+l+m-2}{2})$$

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ・ うへつ

where \mathbf{f} , \mathbf{g} , \mathbf{h} are suitable *p*-adic families of eigenforms specializing to classical eigenforms in classical weights.

My PhD project is related to the construction of a p-adic L-function of three variables (k, l, m) that should interpolate (the algebraic part) of the special values

$$L(\mathbf{f}_k \times \mathbf{g}_l \times \mathbf{h}_m, \frac{k+l+m-2}{2})$$

where \mathbf{f} , \mathbf{g} , \mathbf{h} are suitable *p*-adic families of eigenforms specializing to classical eigenforms in classical weights.

This construction has been already achieved in many cases and with different approaches (some people involved: Andreatta, Bertolini, Darmon, Greenberg, Hsieh, Iovita, Rotger, Seveso, Venerucci, ...) and we would like to generalise it to more general settings.

э

Thanks for the attention ... and moory Christmas !!!
